

# Navigating Phylogenetic Trees using Graphing Algorithms

Giorlando Ramirez

So...What's the problem?

# The solution to our problems?

A Graph, a starting node in the Graph and goal node in the Graph.

Goal node. The shortest path back to starting node.

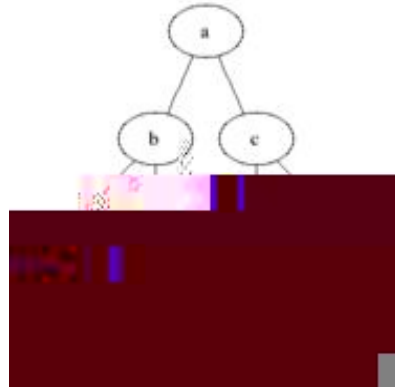

\*Making this function was hard.

# So how does it work?

-Visits neighbor nodes first before moving on to next level neighbors. As opposed to simply going the full depth(Depth first search).

Here's a nice gif to demonstrate exactly how it works:

Gif source: [https://en.wikipedia.org/wiki/Breadth-first\\_search](https://en.wikipedia.org/wiki/Breadth-first_search)

# Data and Formatting

-Works on data sets presented in the Newick format:

Example:

# Results

-The program can:

- Trace the path taken between species.

- Calculate number of edges.

- Find the distance between species.

-Good news: Program works on practice Data Set. And creates nice graph in GraphSpace.

-Bad news: Wasn't able to find a Newick Tree format database to download loads of data directly from. So Data-wise the program is very limited. And I had to build all of the test graphs and corresponding dictionaries.
